36-Month Monte Carlo Value Forecast

Footy-Models · U23 / FM PA ≥ 140 / MV ≤ €1M · FM26 × Transfermarkt · simulated with the repo's own Rust primitives (crates/forecast: Rng64, FootballPathModel, monte_carlo_paths) · 1,000 paths per player · seed 42

Method. Each player's value evolves monthly as a log-normal process. Annual drift = the model's 12-month log forecast annualized (μ = ln(forecast/current)/1y); annual vol = conformal 80% interval width converted to σ (radius 0.591 log-ratio / 1.2816 = 0.461). Driver noise channels (development/performance) are disabled so the simulated dispersion equals the forecast model's uncertainty; the transfer hazard (25%/yr, contract-boosted) and contract bookkeeping come from `FootballPathModel`. 1,000 deterministic paths × 37 monthly points × 36-month horizon. Mean path highlighted; dashed = median; shaded = 10–90% band.
